- 4. [12 points] Parts a. and b. below are unrelated.
 - a. [6 points] Suppose that the temperature in Staunton, Virginia, in degrees Fahrenheit (°F), can be modeled by a sinusoidal function S(t) where t is the time in months since January 1. Note that, for example, August 1 is seven months after January 1. A formula for S(t) is

$$55 - 21 \cos\left(\frac{\pi}{6}t\right),\,$$

i. Using this model, what is the coldest temperature in Staunton?

Solution: The midline of this sinusoidal function is at an output value of 55, and the amplitude is 21. Therefore the lowest value is $55 - 21 = 34^{\circ}$ F.

ii. Using this model, what is the average temperature over the entire year?

Solution: The midline of this sinusoidal function gives us the average temperature, and so the average temperature is 55° F.

iii. At what time t does the temperature first reach "room temperature" (68°F)? Give your final answer in exact form.

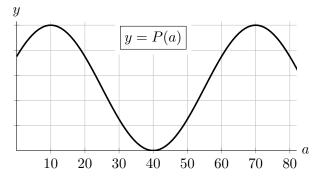

Solution: To find when the temperature first reaches room temperature, we must solve for t in the following equation:

$$55 - 21\cos\left(\frac{\pi}{6}t\right) = 68.$$

Since we are looking for the *first* time the temperature reaches room temperature (and there is no horizontal shift from cosine in the given function), the arccosine function will give us our desired t-value. We therefore solve:

$$55 - 21 \cos\left(\frac{\pi}{6}t\right) = 68$$
$$-21 \cos\left(\frac{\pi}{6}t\right) = 68 - 55$$
$$\cos\left(\frac{\pi}{6}t\right) = -13/21$$
so one solution is given by
$$\frac{\pi}{6}t = \arccos\left(-13/21\right)$$
$$t = \frac{6}{\pi}\arccos\left(-13/21\right).$$

b. [6 points] Suppose that a probe lands on some planet other than Earth, and that its recorded temperature, in degrees Fahrenheit, can be modeled by a sinusdoidal function P(a) where a is the time in years since the probe landed. Note that the scale on the y-axis is unknown.

When the temperature is too cold, the probe is in a state of hibernation. The first time it enters hibernation is at a = 27.

i. At what time a does the probe leave hibernation?

Solution: The probe will leave hibernation the next time after a = 27 that P(a) is equal to P(27). Since P has a minimum at a = 40, its graph is symmetric about the vertical line a = 40, and so the probe will leave hibernation 40 - 27 = 13 years after a = 40. That is to say, the probe will leave hibernation at a = 53.

ii. What is the period of P(a)?

Solution: We observe that the function P has a maximum at a = 10 and another maximum at a = 70. Therefore the period of P(a) is 70 - 10 = 60.

iii. Use the period you found to calculate the next time at which the probe will enter hibernation.

Solution: The probe will next enter hibernation after one period of P(a) has passed since the first time it entered hibernation. Therefore, the probe will next enter hibernation at a = 27 + 60 = 87.
