2. [14 points] Suppose $f(x)$ is a function defined for all real numbers whose derivative and second derivative are given by

$$
f^{\prime}(x)=(x-4)^{3}(x+2)^{2 / 3} \quad \text { and } \quad f^{\prime \prime}(x)=\frac{(11 x+10)(x-4)^{2}}{3(x+2)^{1 / 3}} .
$$

a. [7 points] Find all critical points of $f(x)$ and all values of $x$ at which $f(x)$ has a local extremum. Use calculus to find and justify your answers, and be sure to show enough evidence to demonstrate that you have found all local extrema. For each answer blank below, write NONE if appropriate.

Solution: First we find the critical points, which occur when $f^{\prime}(x)=0$ or $f^{\prime}(x)$ does not exist. From the formula, we can see that $f^{\prime}(x)=0$ when $x=4$ or $x=-2$, and that $f^{\prime}(x)$ always exists.
Next we must determine whether there is a local min, local max, or neither at each critical point. The second derivative test is inconclusive, because $f^{\prime \prime}(-2)$ does not exist and $f^{\prime \prime}(4)=0$. So we must use the First Derivative Test. The factor $(x+2)^{2 / 3}$ is always positive, while $(x-4)$ is negative for $x<4$ and positive for $x>4$. This gives us the resulting signs:

| Interval | $x<-2$ | $-2<x<4$ | $4<x$ |
| :---: | :---: | :---: | :---: |
| Sign of $f^{\prime}(x)$ | $-\cdot+=-$ | $-\cdot+=-$ | $+\cdot+=+$ |

So $f(x)$ has a local minimum at $x=4$ and no local maxima.

## Answer:

$$
\text { Critical point(s) at } x=\ldots-2,4
$$

Local max(es) at $x=$ $\qquad$ Local $\min (\mathrm{s})$ at $x=$ $\qquad$ 4
b. [7 points] Find the $x$-coordinates of all inflection points of $f(x)$. If there are none, write NONE. Use calculus to find and justify your answers, and be sure to show enough evidence to demonstrate that you have found all inflection points.

Solution: First we find the candidate inflection points, which occur when $f^{\prime \prime}(x)=0$ or $f^{\prime \prime}(x)$ does not exist. We can see that $f^{\prime \prime}(x)=0$ at $x=4$ and $-\frac{10}{11}$, and that $f^{\prime \prime}(x)$ is undefined when $x=-2$. To determine whether these are actually inflection points (where concavity changes), we must test the sign of the second derivative on either side of each of point. We find the following:

| Interval | $x<-2$ | $-2<x<-\frac{10}{11}$ | $-\frac{10}{11}<x<4$ | $4<x$ |
| :---: | :---: | :---: | :---: | :---: |
| Sign of $f^{\prime \prime}(x)$ | $\frac{-\cdot+}{-}=+$ | $\frac{-\cdot+}{+}=-$ | $\frac{+\cdot+}{+}=+$ | $\frac{+\cdot+}{+}=+$ |

The inflection points of $f(x)$ occur at the points where the sign of the second derivative changes, that is, at $x=-2$ and $x=-\frac{10}{11}$.

Answer: Inflection point(s) at $x=\quad-2,-\frac{10}{11}$
